(54) Engine

(57) The invention relates to an engine having a crankshaft (9; 13) directed in a vertical direction, comprising a flywheel (58; 32) provided at a lower end of said crankshaft (9; 13) which protrudes from an engine block (20; 19), and an engine mount case (4; 38) coupled to a lower surface of said engine block (20; 19) for mounting said engine (7; 4), said engine mount case (4; 38) having a peripheral wall (-; 37a) which extends to below the flywheel (58; 32) to surround at least a portion of the periphery of said flywheel (58; 32). The arrangement of the mount case (4; 38), the engine block (20; 19) and the elements thereof allows an excellent mountability. So this engine is suitable for use in an outboard motor.

FIG. 14

Description

The present invention relates to an engine preferably to be mounted in an outboard motor. The engine according to the present invention can be utilized not only as an engine for an outboard motor, but also as a general-purpose engine.

In a common type of the prior art outboard motor, an engine (a vertical engine) having a flywheel provided at an upper end of a vertically directed crankshaft protruding from an engine block is mounted in an outboard motor body case which is mounted to boat body through an antivibration mount. Such types of the outboard motors are disclosed, for example, in Japanese Patent Application Laid-open Nos. 191610/87, 192917/88 and 192918/88.

In these outboard motors, a ring gear is mounted around an outer periphery of the flywheel, and a starter motor is mounted above a side of the engine and meshed with the ring gear. A driving pulley of a valve-operating wrapping type transmission is provided at an end of the crankshaft adjacent and below the flywheel.

In usual, an igniting power source coil and a charging power source coil are accommodated in the flywheel to constitute a dynamo and hence, the flywheel is of a downwardly-turned bowl-like shape.

In such prior art outboard motor, the heavy flywheel having a large inertial moment, which largely influences the determination of the gravity center position of the engine, is farther spaced upwardly from the antivibration mount. And the crankshaft end opposite from the flywheel is coupled to a driving shaft for transmitting a driving force to a propeller. Therefore, factors of a torsional vibration are increased to exert not a little influence to the selection of the antivibration mount and hence, the selection of the antivibration mount must be taken into special consideration.

In addition, not only the flywheel but also a starter must be mounted above the engine. Therefore, the gravity center position of the engine becomes high, which increases the moment required during tilting-up of the outboard motor, and also limits the freedom of the disposition of other auxiliaries, especially, the disposition of an electric equipment box for accommodating a CDI unit and a plurality of coils, other auxiliaries such as intake system auxiliaries or the like, in the case of a multi-cylinder (3 or more) engine.

Further, in a 4-cycle engine used in the outboard motor, the driving pulley of the wrapping type transmission is provided as a valve operating device at the crankshaft end adjacent the flywheel. But the crankshaft end requires a large diameter for mounting the flywheel. Therefore, the diameter of the driving pulley must be increased and as a result, a driven pulley adjacent a cam shaft is also increased in size and has a shape occupying an area near an upper portion of a cylinder head, bringing about an increase in size of an upper portion of a rear end of an engine cover spaced from a

tilting shaft. However, this portion of the engine cover is liable to interfere with a boat body structure, when the outboard motor is turned upwardly about the tilting shaft and hence, the unnecessary increase in size of this portion is undesirable and inconvenient even in respect of a moment required for the turning of the outboard motor.

A lower portion of the outboard motor body case is formed narrow in order to reduce the underwater resistance of a submerged portion of the case to the utmost and to provide a reduction in weight. Therefore, an engine having a good mountability to such outboard motor body case is desired.

In Japanese Utility Model Application Laid-open Nos. 21509/91 and 23609/91, there has been proposed an engine in which a crankshaft is directed vertically and a flywheel is provided at a lower end of the crankshaft protruding from an engine block. Such an engine includes a transmission connected to that lower end of the crankshaft which is provided with the flywheel. Thus, this engine can not be applied directly as an engine for use in the outboard motor, and such prior arts do not suggest any means capable of solving problems inherent in the engine of the above-described type for use in the outboard motor.

Accordingly, it is an object of the present invention to provide an engine which is excellent in mountability to the outboard motor body case.

To achieve the object, according to the present invention, there is provided an engine with a crankshaft directed vertically, comprising a flywheel provided at that lower end of the crankshaft which protrudes from an engine block, and an engine mount case coupled to a lower surface of the engine block for mounting the engine, the engine mount case having a peripheral wall which extends to a position below the flywheel to surround at least a portion of the periphery of the flywheel.

With the above construction, notwithstanding the flywheel is provided at the lower portion of the engine, the engine can be easily placed in position through the engine mount case. Particularly, the engine is suitable for use in the outboard motor and can be easily and satisfactorily mounted to the outboard motor body case through the engine mount case.

The above and other objects, features and advantages of the invention will become apparent from the following description of preferred embodiments taken in conjunction with the accompanying drawings.

Figs. 1 to 12 illustrate a first embodiment of the present invention, wherein

Fig. 1 is a side view of the entire outboard motor;

Fig. 2 is a right side view of an engine;

Fig. 3 is a left side view of the engine;

Fig. 4 is a cross-sectional view of the engine;

Fig.18 is a centrally vertical sectional view of an upper portion of an engine cover; and

Fig.19 is a sideways vertical sectional view of the upper portion of the engine cover.

A first embodiment of the present invention will be first described with reference to Figs. 1 to 12.

Fig.1 is a side view of the entire outboard motor to which the present invention is applied. An outboard motor body 1 is mounted at a stern 3 through a mounting means 2. The outboard motor body 1 includes an outboard motor body casing 6 which comprises an engine mount case 4 and an extension case 5. An engine 7 is mounted on an upper portion of the outboard motor body casing 6 and covered at its upper portion with an engine cover 8. The open air is introduced into the cover 8 through an air intake port 8a.

The engine 7 will be described hereinafter. A crankshaft 9 of the engine 7 is directed vertically, and a driving shaft 10 is connected to the crankshaft 9 and extends downwardly within the outboard motor body casing 6. The driving shaft 10 is connected at its lower end to a propeller shaft 12 through a forward and backward movement changing device 11. A propeller 13 is rotatively driven by an engine power transmitted thereto through the crankshaft 9, the driving shaft 10, the forward and backward movement changing device 11 and the propeller shaft 12.

The mounting means 2 includes a bracket 15 fixed to the stern through bolts 14, and a swivel case 17 pivotally mounted on the bracket 15 for vertically swinging movement through a tilting shaft 16 provided at a front end of the bracket 15 to extend transversely. A swivel shaft 18 is rotatably carried in the swivel case 17 in a vertically directed manner. The outboard motor body casing 6 is connected to the swivel shaft 18 through

upper and lower connecting members 19 and 19a. Thus, the outboard motor body casing 6, i.e., the outboard motor body 1 is vertically swingable about the tilting shaft 16 and turnable in counterclockwise and clockwise directions about an axis of the swivel shaft 18.

Fig.2 is a right side view of the engine 7; Fig.3 is a left side view, and Fig.4 is a cross-sectional view. The terms "left" and "right" mean left and right when the outboard motor mounted at the stern 3 is viewed forwardly from rear (rightwardly from left in Fig.1).

An engine body of the engine 7 includes an engine block 20, a cylinder head 21 and a cylinder head cover 22. The engine block 20 is constructed by integrally coupling a cylinder block portion 20a integrally provided with a skirt forming a half of a crankcase, with the remaining crankcase portion 20b by a bolt 23. Two sets of upper and lower pairs of cylinders 24, 24 arranged into a laterally V-shaped configuration are disposed within the engine block 20. More specifically, the engine 7 is a V-type 4-cycle engine with pistons 25 connected to the single crankshaft 9 directed vertically through connecting rods 26.

Fig.6 is a side view of the engine block 20 on the side of the cylinder head 21. As can be seen from Fig.6, the cylinders 24 are four cylinders: a pair of cylinders 24a and 24b vertically arranged on the left side, and another pair of cylinders 24c and 24d vertically arranged on the right side. These cylinders are arranged in a zigzag manner such that the left cylinders 24a and 24b are higher in level than the right cylinders 24c and 24d. Such arrangement of the cylinders makes it possible to reduce the lateral width of the engine block, as compared with another V-type engine and to reduce size of the engine 7.

Intake ports 28 are provided in the cylinder head 21 in correspondence to the cylinders 24, as shown in Fig.4 with regard to the left (left in the outboard motor, i.e., lower as viewed in Fig.4) cylinder 24. The intake ports 28 are connected to the corresponding cylinders 24 through intake valves 29 and open into a side surface of the cylinder head 21. Intake pipes 30 are connected to such openings of the intake ports 28, respectively and extend along the side surface of the engine block 20 toward a crank chamber provided ahead. The intake pipes 30c and 30d shown in Fig.2 are those corresponding to the cylinders 24c and 24d shown in Fig.6, and the intake pipes 30a and 30b shown in Fig.3 are those corresponding to the cylinders 24a and 24b shown in Fig.6.

Surge tanks 31L and 31R are provided on the laterally opposite sides of a front portion of the engine block 20, and the intake pipes 30a and 30b are in communication with the surge tank 31L, while the intake pipes 30c and 30d are in communication with the surge tank 31R. On the other hand, a throttle body 32 having a throttle valve there in is disposed on a front and central portion of the engine block 20, and is in communication with the surge tanks 31L and 31R through an air passage 33

which diverges laterally from the throttle body 32. Air is introduced from above into the throttle body 32 via an air introducing pipe 34.

The air introduced from above via the air introducing pipe 34 is adjusted in flow rate within the throttle body 32 and then distributed into the left and right surge tanks 31. From the tanks 31, the air is supplied as combustion air through the intake pipes 30 into the corresponding cylinders 24, wherein fuel is injected from a fuel injection valve 35 and mixed with such air in the intake ports 28 (Fig.4). In Fig.2, reference character 32a is a throttle valve stem; reference character 32b is a link member; and reference character 32c is a fastener of a rubber or the like. In Fig.3, reference character 32d is a throttle valve opening degree sensor, and reference character 33b is an intake air temperature sensor.

The surge tank 31 has a connection 33a to the air passage 33 on a side thereof, and has a capacity area extending vertically, i.e. upwardly and downwardly of the connection 33a. The volume of the capacity area is set as required, but a portion of the capacity area lying below the connection 33a is located out of a flow of air from the connection 33a to a connection with each intake pipe 30. Hence, should water enter an intake system, such portion also acts as a separating chamber. Reference character 93 is a drain bolt.

Fig.5 is a diagram illustrating a fuel supply system. Reference character 37 is a fuel receiving pipe mounted in the outboard motor, and reference character 38 is a fuel delivering pipe mounted on a boat. By connecting these pipes 37 and 38, the fuel can be supplied from a fuel tank 39 mounted on the boat. Reference character 40 is a low-pressure filter, and reference character 41 is a low-pressure pump. The fuel pumped from the fuel tank 39 by the low-pressure pump 41 is once stored in a gas-liquid separator 42 and then supplied via a strainer 43, a high-pressure pump 44 and a high-pressure filter 45 to the fuel injection valve 35. These devices and pipes mounted on the outboard motor are disposed on the left side of the engine, as shown in Fig.3. The high-pressure pump 44 may be disposed within the gas-liquid separator 42.

An exhaust valve 46 is mounted below the intake valve 29 in each of the cylinders 24 (see Fig.4), and an exhaust passage 47 is defined in the cylinder head 21 to lead to each of the exhaust valves 46. The exhaust passages 47 extend vertically through a widthwise central portion of the cylinder head 21, i.e., through an intermediate section between the array of the left cylinders 24a and 24b and the array of the right cylinders 24c and 24d to meet together at lower ends and open into the lower surface of the cylinder head 21 (see Figs.7 and 12). A valve operating mechanism comprising a cam 89a and a rocker arm 90a for the intake valves 29, and a cam 89b and a rocker arm 90b for the exhaust valves 46 is shown in Fig.12 only for the cylinders 24a and 24d, but of course, a similar valve operating mechanism is mounted for each of the other cylinders.

As shown in Fig.2, a starter motor 48 is mounted on the right side of the engine block 20 with its output shaft 49 protruding downwardly. A driving gear 50 is mounted to the output shaft 49 and meshed with a ring gear which is integrally formed around an outer periphery of a flywheel which will be described hereinafter.

Fig.7 is a view of the engine 7 taken in various vertical sections including an axis of the crankshaft 9, with a section of the cylinder 24c and a portion of a section of the cylinder 24b being shown.

The crankshaft 9 is directed vertically, as described above, and a cam shaft 51 is disposed in the cylinder head 21 in parallel to the crankshaft 9. Upper ends of the crankshaft 9 and the cam shaft 51 are passed through the engine block 20 and the cylinder head 21, respectively to project upwardly. Pulleys 52 and 53 are fixedly mounted at these upper ends. A belt 54 is wound around the pulleys 52 and 53. Thus, the cam shaft 51 is driven by the crankshaft 9 through the belt 54. Since the engine 7 is the 4-cycle engine, the diameter of the pulley 53 is twice the diameter of the pulley 52 in order to set the rotational ratio of the crankshaft 9 to the cam shaft 51 at 2 : 1. Reference characters 52a and 53a are controlling pick-up plates.

A lower surface of the engine block is formed into an open portion 55, and a lower wall of the engine block 20 is formed by a closing plate 56 for sealingly closing the open portion 55. The closing plate 56 is detachably secured to the engine block 20 by bolts 57 (Figs.2 and 3). A lower end of the crankshaft 9 is rotatably passed through to project downwardly, and a flywheel 58 is secured to such lower end.

Fig.8 is an enlarged view of a portion in the vicinity of the flywheel 58 shown in Fig.7. An axial bore 59 is provided in the lower end of the crankshaft 9, and a collar member 60 is fitted in the bore 59. A circumferentially projecting annular flange 60a is formed at a lower end of the collar member 60. The flywheel 58 is secured to the crankshaft 9 by fitting a circular bore centrally provided in a bottom plate portion 58a thereof over the collar member 60 and sandwiching their peripheral portions between a lower end face of the crankshaft 9 and the flange 60a to clamp them together by a bolt 61. The collar member 60 is also integrally fixedly secured to the crankshaft 9 by the bolt 61.

The flywheel 58 has a peripheral wall 58b projecting upwardly along an outer peripheral edge of the bottom plate portion 58a and is formed into a dish-like shape as a whole. A dynamo 64 is mounted within a space surrounded by the peripheral wall 58b and includes a rotor 62 fixed to the flywheel 58 and a starter 63 fixed to the closing plate 56.

Further, a ring gear 65 is integrally formed around an outer periphery of the peripheral wall 58b of the flywheel 58 by shrink-fitting of a gear portion or by another means. The ring gear 65 is meshed with the driving gear 50 provided on the output shaft 49 of the starter motor 48 (Fig.2), and at the start of the engine, the

crankshaft 9 is driven by the starter motor 48.

The engine mount case 4 is coupled to the lower surface of the engine block 20 along with the closing plate 56 interposed therebetween by clamping thereof using the bolts 57. (In Fig. 7, reference character 91 is a shift rod, and reference character 92 is a shift rod operating member connected to the shift rod through a link system not shown, and Fig. 8 is another sectional view of these portions and the bolt 57 is shown.) The engine mount case 4 extends further rearwardly up to the vicinity of the cylinder head, and is also connected to the lower surface of the cylinder head 21 into which the exhaust passage 47 opens. Fig. 9 is a top view of the engine mount case 4, where in reference characters 66a and 66b are packing surfaces extending along and abutting against the peripheral edge of the closing plate 56. A packing surface 67 is further provided to divide a space surrounded by the packing surfaces 66a and 66b into front and rear sections. The rear portion of the engine mount case 4 is in abutment against the lower surface of the cylinder head 21 through the packing surface 68 and is provided with an exhaust passage 69 communicating with the exhaust passage 47.

The engine mount case 4 has peripheral walls 70a and 70b extending downwardly from the packing surfaces 66a and 66b, respectively, and an enclosure wall 71 extending downwardly from the packing surface 67 (Fig. 7). All of the peripheral walls 70a and 70b and the enclosure wall 71 extend to positions lower than the flywheel 58. The periphery of the flywheel 58 is surrounded by the peripheral wall 70b and the enclosure wall 71. The lower end of the peripheral wall 70a is connected to a bottom plate 72a, and the lower end of the peripheral wall 70b is connected to a bottom plate 72b. These bottom plates 72a and 72b extend to positions below the central portion of the flywheel 58. However, the height (i.e., depth) of the peripheral wall 70b as measured from the packing surfaces 66a, 66b and 67 is lower than the height (i.e., depth) of the peripheral wall 70a and hence, the bottom plates 72b and 72a are superposed on each other in a vertically spaced apart relation below the central portion of the flywheel 58, and a mounting front opening 73 is defined therein to open forwardly.

The driving shaft 10 for transmitting the rotation of the crankshaft 9 to the propeller 13 is carried in the bottom plates 72b and 72a to vertically extend through the opening 73. An upper end of the driving shaft 10 is inserted from below into an internal bore 60b (Fig. 8) in the collar member 60 fitted to and spline-engaged with the crankshaft 9.

The connecting member 19 for connecting the swivel shaft 18 and the engine mount case 4 to each other is also inserted from front into the opening 73. The connecting member 19 includes two left and right connecting rods 19a and 19b to extend longitudinally on opposite sides of the driving shaft 10. Tip ends of the connecting rods 19a and 19b are connected to the

engine mount case 4 through a mount rubber 74.

Fig. 10 is a plan view of the engine mount case as viewed from below. A mounting surface 75 is formed into an annular shape on the lower surface of the engine mount case 4 (lower surface of the bottom plate 72a). Thus, the engine 7 is mounted on the extension case 5 through the engine mount case 4 by clamping the engine mount case 4 to the peripheral edge of the upper end of the extension case 5 with the mounting surface 75 interposed therebetween.

An annular oil pan mounting surface 76 is also formed on the lower surface of the engine mount case 4 inside the mounting surface 75, and a peripheral edge of an upper end of an oil pan 77 is fastened to the oil pan mounting surface 76 by bolts 78, as shown in Fig. 7. An opening 79 in an upper surface of the oil pan 77 communicates with the inside of the engine block 20 through an oil communication passage 80 defined in the engine mount case 4 and an opening 81 provided in the closing plate 56. And an oil returned from the crank chamber and accumulated on the closing plate 56 is passed through the opening 81 and the oil communication passage 80 and dropped from the opening 79 into the oil pan 77. However, the opening 81 is provided on the side opposite from the flywheel 58 with respect to the enclosure plate 71 of the closing plate 56. Therefore, the oil on the closing plate 56 cannot enter a portion of the flywheel 58 which is surrounded by the peripheral wall 70b and the enclosure wall 71.

An exhaust pipe portion 77a is integrally formed at an upper portion of the oil pan 77 to protrude rearwardly, and an exhaust passage 82 is defined in the exhaust pipe portion 77a to communicate with the exhaust passage 69 in the engine mount case 4. The exhaust passage 82 communicates with a catalytic converter 83 juxtaposed outside the oil pan 77, and an exhaust gas purified in the catalytic converter 83 is passed through an exhaust pipe 84 and discharged from the lower portion of the extension case 5 into water.

The oil stored in the oil pan 77 is drawn through a strainer 85 and an intake pipe 86 into an oil pump 87 and supplied from the oil pump 87 to various portions of the engine. The oil pump 87 is driven by the crank shaft 9 through a gear train 88 (see Fig. 8).

In general, the gravity center of the outboard motor body is offset toward the gravity center of the engine due to an influence of the heavy engine carried at the upper portion and is at a location higher than the tilting shaft. In the above-described embodiment, however, the flywheel 58 which was located at the uppermost portion of an engine in the prior art, is now provided at the lower end of the crankshaft 9, i.e., at the lower portion of the engine 7. Therefore, the gravity center of the engine 7 and thus the gravity center of the outboard motor body 1 is lowered to a position near the tilting shaft 16. Therefore, only a reduced moment is required to swing the outboard motor body 1 upwardly about the tilting shaft 16, thereby enabling an easy tilting-up or a

prompt tilting-up.

The flywheel 58 provided at the lower portion of the engine 7 is accommodated in a space between the engine block 20 and the connecting member 19. Therefore, the entire height of the outboard motor body 1 is relatively low. Further, the flywheel does not exist above the pulley 52 and hence, even if the pulley 52 is made sufficiently small in diameter, there is no problem in handling the pulley. Thus, the pulley 53 may be of a small diameter, leading to a reduction in size of the outboard motor body 1.

Notwithstanding that the flywheel 58 protrudes downwardly, the engine 7 can be easily placed at a predetermined location through the engine mount case 4 having the peripheral wall 70 extending to a position below the flywheel 58 and particularly, can be easily and satisfactorily mounted on the outboard motor body 1.

In addition, since the flywheel 58 has the upper and lower portions covered by the closing plate 56 and the bottom plate 72, and its periphery is covered by the peripheral wall 70b and the enclosure wall 71, water or the like is difficult to enter the area of the flywheel 58 from the outside and hence, the dynamo can be mounted without any influence exerted to portions around the dynamo 54.

Further, the engine 7 in the present embodiment can also be utilized as a horizontal power source with the crank shaft 9 directed horizontally, by sealing the opening 81 in the closing plate 56, or by replacing the closing plate 56 itself and removing the oil pan 77.

In the starter motor 48 of the engine 7, the output shaft 49 thereof protrudes downwardly from the motor body to engage, from above, the ring gear 65 formed on the flywheel 58 located below the starter motor 48 and hence, the need for water-proofness of such portion of the motor 48 can be avoided or reduced.

In the engine 7, the power take-off driving shaft 10 and the flywheel 58 are mounted at the same end of the crankshaft 9 and therefore, the vibration of the engine due to the crankshaft 9 is reduced.

A second embodiment of the present invention will now be described with reference to Figs. 13 to 19. Reference numerals used in the first embodiment are basically different from those used in the second embodiment, and the same reference numeral may not necessarily designate the same element.

Fig. 13 is a side view of the entire outboard motor 1 to which the present invention is applied. Reference character 1a is an outboard motor body casing which includes an extension case 2, a gear case 3 and the like. An engine 4 is mounted at an upper portion of the outboard motor body casing 1a and has an upper portion covered with an engine cover 5.

The outboard motor 1 is mounted at a stern 7 through a mounting means 6. The mounting means 6 includes a bracket 8 fixed to the stern 7 through bolts, and a swivel case 10 pivotally mounted for vertically swinging movement to the bracket 8 through a tilting

shaft 9 mounted to laterally extend over the entire length of the bracket 8. A swivel shaft 11 is rotatably carried in the swivel case 10 in a vertically directed manner. The outboard motor 1 is connected to the swivel shaft 11 through upper and lower connecting members 12 and 12a. Thus, the outboard motor 1 is swingable vertically about the tilting shaft 9 and turnable laterally about an axis of the swivel shaft 11.

The engine 4 has a crankshaft 13 vertically directed, and a driving shaft 14 is connected to the crankshaft 13 and extends downwardly within the extension case 2 to reach the inside of the gear case 3. The driving shaft 14 is connected at its lower end to a propeller shaft 16 through a forward and backward movement changing device 15 within the gear case 3. A propeller 17 is rotatively driven by an engine power transmitted via the crankshaft 13, the driving shaft 14, the forward and backward movement changing device 15 and the propeller shaft 16. Reference character 18 is an operating shaft for changing the forward and backward movements, which is rotatably provided to extend upwardly through the swivel shaft 11.

Fig. 14 is a vertical sectional view of the engine 4. The crankshaft 13 is directed vertically, as described above. As can be seen from Fig. 13, the engine 4 is mounted with the crankshaft 13 located toward a front portion of the outboard motor 1 (toward a boat). In Fig. 14, the right side corresponds to the front side of the outboard motor 1.

An engine body of the engine 4 includes a main block 19, a cylinder head 20 and a cylinder head cover 21. The main block 19 is constructed by integrally connecting a cylinder block 19a integrally provided with a skirt forming a half of a crankcase with a remaining crankcase portion 19b by bolts 22a (Figs. 16 and 17). Four cylinders 23 are arranged in a row within the main block 19. Thus, the engine 4 is an in-line type 4-cylinder and 4-cycle engine, in which pistons 24 are connected to the vertically directed single crankshaft 13 through connecting rods 25. The crankshaft 13 is rotatably carried in the main block 19 in a manner that it is fastened by bolts 22b mounted in the cylinder block 19a and crankcase portion 19b and is sandwiched between opposed bearings.

A cam shaft 27 is vertically disposed within a valve operating chamber 26 defined in the cylinder head 20. The cam shaft 27 is driven by the crankshaft 13 through a wrapping type transmission 31 which includes a driving pulley 28 mounted at an upper end of the crankshaft 13 protruding from the main block 19, a driven pulley 29 mounted at an upper end of the cam shaft 28 protruding from the cylinder head 20, and a belt 30 wound around the pulleys 28 and 29. The cam shaft 27 is in engagement with intake and exhaust valves for every cylinder 23 through rocker arms to control the motions of these intake and exhaust valves. That is, the wrapping type transmission 31 forms a portion of a valve operating device for the engine 4.

The driving shaft 14 is connected to a lower end 13b of the crankshaft 13 protruding from the main block 19 and extends downwardly within the extension case 2, as described above. A disk-like flywheel 32 is further fastened to the lower end 13b by screws 33 to extend parallel to a lower surface of the main block 19. A dynamo 34 is mounted at the upper end 13a of the crankshaft 13 above the valve-operating driving pulley 28, with its rotor 35 fastened to the upper end 13a by a screw 36, so that it is rotated in unison with the crankshaft 13.

In this embodiment, the flywheel 32 is formed into a relatively thin disk-shape, and a low-level skirt portion (an upper case portion) 37 is integrally formed at a lower portion of the main block 19 and opens downwardly. The flywheel 32 is accommodated within the skirt 37. A mount case (lower case portion) 38 is mounted to a flat lower surface of the skirt portion 37 by bolts. The engine 4 is mounted in the extension case 2 through the mount case 38. The skirt portion 37 is provided with an enclosure wall 37a which surrounds an outer periphery of the flywheel 32.

The flywheel 32 basically has a required inertial mass only by itself, but is capable of distributing the inertial mass, inclusive of the rotor 35.

The rotor 35 is vertically high in level, as compared with the flywheel 32, but has a smaller diameter and has an inertial mass far smaller than that of the flywheel 32. Therefore, the diameter of the crankshaft end 13a adjacent the rotor 35 can be reduced and as a result, the diameter of the driving pulley can be reduced. If the diameter of the driving pulley is reduced, the diameter of the driven pulley 29 requiring a diameter twice the diameter of the driving pulley can be correspondingly reduced, which is convenient for compactness of the engine.

The wrapping type transmission 31 and the dynamo 34 are covered from above with a cover member 40. The cover member 40 is formed in a manner that a portion corresponding to the dynamo 34, i.e., a portion near the front portion of the engine 4 is raised, and a rear portion is lowered to extend along the wrapping type transmission 31. The entire cover member 40 shown is integrally formed. But the cover member 40 may be vertically divided into a portion which covers the wrapping type transmission 31, and a portion which covers the dynamo 34, or longitudinally divided into a portion which covers a rear portion of the wrapping type transmission 31, and a portion which covers a front portion of the wrapping type transmission 31 and the dynamo 34.

Below the main block 19, a portion of the skirt 37 enclosing the outer periphery of the flywheel 32 by the enclosure wall 37a protrudes in a circular shape on opposite sides and forwardly (Figs. 16 and 17). A similar protruding portion 38a is also provided on an upper and front portion of the mount case 38 in a face-to-face relation to this protruding portion of the skirt 37 (Figs. 14 and

16). An opening in the protruding portion of the skirt 37 is closed from below by the protruding portion of the mount case 38. This protruding configuration results in an enhanced rigidity of a surrounding portion.

An oil pan 57 is mounted in a depending or hanging-down manner on a flat lower surface of the mount case 38 formed below the protruding portion and near a rear portion, and is accommodated in the extension case 2. The inside of the mount case 38 is divided into a portion 38b defining an accommodating chamber for the flywheel 32 and a portion 38c communicating with the oil pan 57 by a partition wall 58 abutting against an end face of the enclosure wall 37a.

As shown in Fig. 16, the mount case 38 is fastened on its lower surface to an upper end of the extension case 2 by bolts 76. More specifically, the engine 4 is mounted in the extension case 2 through the mount case 38 and accommodated in an engine room 41 having at its upper portion defined by the engine cover 5, but a lower portion of the engine room 41 is defined by an undercase 77 (Figs. 13, 15 and 16) which is supported at a peripheral edge of its lower end on the mount case 38 to cover the lower portion of the engine and which opens upwardly. Fig. 15 is a view of the inside of the engine room 41 as viewed from the opposite side from Figs. 13 and 14 in vertical section of the cover member covering the engine 4, wherein the lower portion of the engine 4 is shown in a sectional view similar to that of Fig. 14.

The engine cover 5 is detachably mounted to the undercase 77 through a mating face 78 to cover an opening provided in an upper portion of the undercase 77. The outer peripheries of the mount case 38 and the extension case 2 in the vicinity of their connection is covered by an undercover 80 which is fastened to the undercase 77 by a screw 79 (Fig. 15), and the outboard motor body 1a has a gentle profile provided by the under case 77, the under cover 80 and the extension case 2.

The upper surface of the engine cover 5 is formed into a shape corresponding to the cover member 40 (Figs. 15, 18 and 19). More specifically, the engine cover 5 is formed in such a manner that a front portion 5a thereof corresponding to the dynamo 34 is higher in level, and a rear portion 5b of the cover 5 is lower in level. An air intake device 42 having a pair of left and right passage members 43 is disposed on this rear portion 5b formed at the lower level. As shown in Fig. 19, each of the passage members 43 is connected to a peripheral edge of an opening 5c provided in the engine cover portion 5b and extends upwardly, and further has a notched air introducing portion 43a provided at an upper opening edge.

The passage members 43 are covered at their upper portions with a cover member 45. The cover member 45 is fixed to the engine cover 5 by a bolt 44 at an intermediate forward position between the left and right passage members 43. The cover member 45

includes an upper plate portion 45a which covers the upper portion of the passage member 43, and a side plate portion 45b pendent along laterally opposite edges of the upper plate portion 45a. The passage member 43 arises on the lower engine cover portion 5b extends behind the dynamo 34 up to the substantially same level as the dynamo 34, so that it is suspended with the dynamo 43 laterally. An upper surface of the cover member 45 rearwardly extends flush with the upper surface of the front engine cover 5a without protrusion from the upper surface of the front engine cover 5a.

The open air is permitted to freely flow through a rear opening into a space defined above the engine cover portion 5b covered at its upper portion and opposite sides by the cover member 45, and is guided via the passage members 43 into the engine room 41 as shown by an arrow a in Fig.18. Such air is used as an intake gas for the engine 4 to cool the periphery of the engine.

Fig.17 is a schematic plan view illustrating the arrangement of the engine 4 and auxiliaries within the engine room 41. Reference character 46 is an intake valve; 47 is an exhaust valve; and 48 is a rocker arm. A valve mechanism comprising these members is provided for every cylinder 2 and controlled in opening and closing by the cam shaft 27. Reference character 49 is an intake port provided in the cylinder head 20. An intake pipe 50 is connected to the intake port 49 and extends forwardly along the side of the engine 4. A portion of air introduced via the passage members 43 into the engine room 41 is drawn into the intake pipe 50 at a front end thereof and then via the intake port 49 into the cylinder 23. Reference character 51 is a carburetor, and 51a is an intake silencer. Such intake pipes 50 are provided for all cylinders 23 and vertically juxtaposed along the side of the engine 4.

At the other side of the engine 4, an exhaust passage 52 extends vertically, and an exhaust port 53 corresponding to each of the cylinders 23 is in communication with the exhaust passage 52. The exhaust passage 52 is connected to an upper end of an exhaust pipe (not shown) extending vertically within the extension case 2, so that an exhaust gas is passed through the exhaust pipe and released at a lower end of the exhaust pipe into water.

On the same side of the engine as the exhaust passage 52, an electric equipment box 54 in which electric equipments are accommodated forwardly, and a starter motor 55 is disposed below the box 54 (see Figs.15 and 16). Reference character 54a is a spark plug cord which is connected to a spark plug provided in the side of the cylinder head 20. An igniting coil 54b, a CDI unit 54c and the like are accommodated in the electric equipment box 54, but since the engine in the present embodiment is the 4-cycle and 4-cylinder engine, the ignition can be achieved by two coils 54b in total, one for two cylinders. These coils are disposed reasonably in a space above the starter motor 55, and the CDI unit 54c

is disposed in a location closer to the front, which would not interfere with the starter motor 55. An output shaft 55a of the starter motor 55 is gear-meshed with a ring gear 56 (Figs.14, 15 and 16) which is mounted around the outer periphery of the flywheel 32.

As shown in Fig.14, an oil intake pipe 60 having a strainer 59 at a lower end thereof extends upwardly from a bottom of an oil pan 57 through an oil pan communication portion 38c of the mount case 38 and is connected to an oil intake passage 61 defined in a lower portion of the main block 19. The oil intake passage 61 is in communication with an intake port 63 in an oil pump 62 which is provided at the lower end of the cam shaft 27 and driven by the cam shaft 27.

An oil pressurized by the oil pump 62 is fed to various bearing portions around the cam shaft 27 and via an oil passage (not shown) provided through the cylinder head 20, the cylinder block 19a and the crankcase 19b to an oil filter 68 mounted to the front surface of the crankcase 19b. The oil leaving the oil filter 68 flows into an oil passage 69 (see Fig.17) vertically located in a laterally central portion of the front surface of the crankcase 19b and is further passed through an oil passage 70 to reach main bearings 39 of the crankshaft 13 to lubricate these bearings.

Further, the oil flows through an oil passage 72 provided in the crankshaft 13 to reach a crank pin bearing 71 and the inside of the cylinder 23 to lubricate the crank pin bearing 71 and the inner surface of the cylinder. The cylinders 23 vertically arranged in a row are in communication with one another at locations closer to the crank chamber through oil bores 73, so that the oil in each cylinder 23 flows down in sequence through these oil bores 73 and is discharged from the lowermost oil bore 73a to a portion in the vicinity of the lower end of the crank shaft 13. However, this oil cannot flow into a chamber accommodating the flywheel 32, and is permitted to flow through an oil passage 82 (Fig.16) for returning of the oil between the main bearing 39 at the lower end and a crankshaft oil seal 81 and through a return oil passage 83 (Fig.16) for returning of the oil around the outside of the flywheel accommodating chamber to the oil pan communication portion of the mount case 38 and then returned into the oil pan 57.

The oil which has lubricated the portion around the cam shaft 27 is passed through an oil passage 74 to an oil return bore 65 and returned via an oil return passage 64 and an oil return pipe 66 to the oil pan 57. The oil pan 57 depends from the mount case 38 into the extension case 2, thereby ensuring that the height of engine 4 mounted cannot be increased. A drain plug 84 is provided at a front end of the bottom of the oil pan 57 to face a recess 85 defined in the extension case 2, as shown in Fig.15. Alternatively, a recess 85 may be provided in the side of the extension case 2 to face the drain plug 84.

The mount case 38 is connected to the pair of left and right connecting members 12 (Fig.13) through a

mount rubber 75 which extends laterally. The mount rubber 75 includes a core member 75a and a rubber 75b which surrounds the core member 75a, and the connecting member 12 is connected to the core member 75a by a bolt.

Claims

1. An engine having a crankshaft (9; 13) directed in a vertical direction, comprising a flywheel (58; 32) provided at a lower end of said crankshaft (9; 13) which protrudes from an engine block (20; 19), and an engine mount case (4; 38) coupled to a lower surface of said engine block (20; 19) for mounting said engine (7; 4), said engine mount case (4; 38) having a peripheral wall (-; 37a) which extends to below the flywheel (58; 32) to surround at least a portion of the periphery of said flywheel (58; 32).
2. The engine according to claim 1, wherein said engine block (20; 19) is detachably provided at its lower surface with a closing plate (56; -) for closing an open portion of said engine block (20; 19), an upper end surface of said peripheral wall (-; 37a) of said engine mount case (4; 38) is abutted against said closing plate (56; -) and coupled thereto, and said engine mount case includes a bottom plate portion (70b; 38b) for covering a lower portion of said flywheel (58; 32), and an enclosure wall portion (70b; 38a) for surrounding the entire periphery of said flywheel (58; 32) in cooperation with said peripheral wall (-; 37a).
3. The engine according to claim 2, wherein said engine mount case (4; 38) is formed at a lower surface thereof with an annular oil pan (77; 57) mounting surface (-; 38a) which extends to a location below said flywheel (58; 32), said closing plate (56; -) having an opening (79; -) provided on the opposite side from said flywheel (58; 32) with respect to said enclosure wall portion (70b; 38a), and said engine mount case (4; 38) is formed with an oil communication passage for permitting the communication between said opening (79; -) and said oil pan (77; 57).
4. The engine according to claim 2 or 3, further including a dynamo (64; -) provided in said flywheel (58; -).
5. The engine according to any one of claims 1 to 4, wherein said flywheel (58; 32) is integrally formed at an outer periphery thereof with a ring gear (65; 56), and a starter motor (48) is disposed above said ring gear (65; 56), said starter motor (48; 55) having a downwardly protruding output shaft (49; 55a) and a driving gear provided on said output shaft and meshed with said ring gear (65; 56).
6. The engine according to claim 5, further including an engine mount case (4; 38) member coupled to the lower surface of said engine block (20; 19), said engine mount case member extending to below said flywheel (58; 32) and having an engine mounting surface on a lower surface thereof.
7. The engine according to claim 3, wherein the oil passage (80, 81; 64, 65) is formed in said engine mount case (4; 38) such that said oil passage (80, 81; 64, 65) being separated from the space accommodating said flywheel (58; 32) by means of a wall (71; 37a, 58).
8. The engine according to claim 7, wherein an oil pump (87; -) is disposed between an engine block (20; -) of the engine body (20, 21, 22; -) and the engine mount case (4; -) (see Figs. 7 and 8).
9. The engine according to claim 7 or 8, wherein said oil pump (87; -) is located at a lower portion of an engine block (20; -) of the engine body (20, 21, 22; -) (see Figs. 7 and 8).
10. The engine according to claim 7, wherein an oil pump (-; 62) is located at a lower portion of a cylinder head (-; 20) of the engine body (-; 19, 20, 21) (see Fig. 14).
11. An outboard motor comprising an engine according to anyone of claims 1 to 10.
